From Excel to Intelligence

THE PROBLEM WITH SPREADSHEETS

No real-time availability

Two staff members open the same file. Both book Table 27 for 8:00 PM Saturday. You discover the conflict at the door.

Zero guest memory

A VIP who visits every week is treated like a stranger on every call. No visit history, no preferences, no recognition.

Manual everything

Date calculations, column sorting, status tracking — every update is a manual step that can be wrong or missed.

Analytics don't exist

Which time slot fills fastest? Which guests no-show most? Which table is least used? Excel cannot answer these in real time.

No call intelligence

When a guest calls, staff scramble to search the file. The guest waits. Details get missed or mis-recorded.

Disconnected workflow

Reservations, waitlist, orders, staff notes, inventory — all in separate files, never talking to each other.

WHAT SEATED CHANGES

Seated replaces every spreadsheet with a live, role-aware dashboard — purpose-built for the pace of a restaurant service.

CORE RESERVATION ENGINE

Smart Reservation Creation

Create bookings in seconds — name, phone, date, time, party size, table, and notes in one form. The system auto-selects the right time slots for the day of week (weekday, weekend, Ramadan schedules).

Multi-table booking

Time slot auto-config

Walk-in mode

Double-Booking Prevention (Enforced at Database Level)

The system checks for conflicts before saving any reservation — not just in the browser but at the server, so two staff opening the same form simultaneously cannot create a conflict. If a table is taken, the booking is rejected with a clear error.

Backend-enforced

Real-time

Concurrent-safe

Live Reservation Dashboard

Active, Completed, and Cancellations & No-Shows in separate tabs. Filter by today, tomorrow, this week, or pick any date. Search by name, phone, or table instantly.

Grid & list views

Slot-based tabs

All-time cancellations view

Status Lifecycle Tracking

Booked !' Confirmed !' Seated !' Completed, with one-tap transitions. Cancelled and No-show statuses include undo support. The system records what status a reservation held before becoming a no-show.

Status history

Undo complete

No-show tracking

Platform Features — Continued

Guest Directory

Every guest auto-saved with visit count, party history, and lifetime covers. Repeat-guest rate, favourite time slots, and no-show count tracked automatically.

Waitlist Management

Live queue with join time, estimated wait, and one-tap seat. Walk-in seating flows directly into the reservation system with no duplicate entry.

Incoming Call Tracker

Log a phone number and instantly see the caller's full history — last booking, visit count, whether they're new or returning — before the conversation ends.

Order Management

Table-based order creation with category browsing, search, and quantity controls. Links to today's reservation automatically. Open and closed order tracking.

Menu Management

Full menu CRUD by category. Powers the order system and analytics. Add, edit, or remove items without touching code.

Table Overview

See every table's live status — free, booked, or seated — for the selected date and time. Navigate by slot. Colour-coded occupancy at a glance.

GOOGLE SHEETS INTEGRATION

Automatic sync — no manual export needed.

Every new reservation is written to the correct tab and row in your Google Sheet the moment it is created. Status changes (seated, cancelled, no-show) update the sheet row in real time. A manual full export is always one click away for auditing.

Performance

- Total covers and reservations for any date range
- Average party size and covers-per-day
- Table utilisation rate (booked vs available)
- Busiest day, day of week, and time slot

Guest Behaviour

- Repeat guest rate (walk-ins excluded to keep data clean)
- Top returning guests by visit count and lifetime covers
- Walk-in volume, peak slot, and share of total bookings

No-Show Intelligence

- Total no-shows and no-show rate
- Confirmed !' no-show vs Booked !' no-show breakdown (who confirmed but still didn't come)
- Peak no-show time slot (which slot is highest risk)
- Top no-show guests ranked by frequency

Cancellation Tracking

- Cancellation rate across all reservations
- Filter cancellations by today, a specific date, a date range, or all time
- Full historical record always accessible in one tab

All analytics respond to the date filter — all time, a single day, or a custom range. Walk-ins are automatically separated from regular guests to prevent inflating repeat guest and return rate figures.

Efficiency Gains vs Excel

Task	With Excel	With Seated
Check table availability for a time slot	Open file, scroll, manually scan rows	Instant — table grid shows live colour-coded status
Avoid a double booking	Hope no one else books while you're in the file	Server-side lock — physically impossible to double-book
Identify a returning guest on a call	Search the sheet by name or phone while the caller waits	Log the number — full history appears in under 1 second
See tonight's bookings by time slot	Filter, sort, and format — 5+ steps	Dashboard loads in the correct slot view by default
Track how many no-shows you had last month	Manual count or a pivot table	Analytics page — filter by range, read the number
Move a guest from the waitlist to a table	Delete from waitlist, add to reservations — 2 files	One-tap Seat — creates the reservation automatically
Sync reservation data to Google Sheets	Already in a sheet (with no structure)	Automatic — writes to the correct tab and row on save
Know which time slot is most popular	Build a formula or pivot table	Analytics page — slots sorted by cover volume

The result: less time administrating, more time with guests.

Every feature was designed to remove friction from service — not add another tool to manage.

Build Story & Version Evolution

HOW IT WAS BUILT

Seated was built iteratively — every feature was shaped by real operational feedback from PAOLA's Cosa Nostra. The product grew from a basic booking form to a full restaurant intelligence platform across dozens of focused build sessions.

Phase 1 — Foundation

Initial build

- Core reservation creation, editing, and deletion
- Guest directory with automatic visit tracking
- Table availability view with occupied/free states
- Google Sheets export for the existing team workflow

Phase 2 — Operations

Service workflows

- Real-time waitlist with estimated wait times and one-tap seating
- Walk-in reservation mode — seated immediately without pre-booking
- Order management system with menu categories and table linking
- Menu CRUD page for direct management without developer access
- Incoming call log with instant guest lookup by phone number
- PostgreSQL persistence replacing in-memory storage

Phase 3 — Intelligence

Analytics & insights

- Full analytics dashboard: covers, slots, day-of-week patterns, table utilisation
- Repeat guest rate, top returning guests, walk-in separation
- No-show analytics: total rate, peak slot, top offenders, status transition breakdown
- Date filtering across all analytics views (day / range / all time)
- Walk-in detection improved to handle all creation sources and name variations

Phase 4 — Reliability

Hardening & polish

- Backend-enforced double-booking prevention (database-level, not just UI)
- Cancellations tab with independent date filter (today / date / range / all time)
- Status history tracking: records previous status before a no-show is marked
- Undo Completed — reverse accidentally-completed reservations back to Seated
- Login page and session-based authentication for access control

Technical Snapshot & Next Steps

WHAT POWERS SEATED

Frontend	React 18 + TypeScript, TanStack Query, shadcn/ui, Tailwind CSS
Backend	Node.js + Express, RESTful API with full input validation
Database	PostgreSQL with Drizzle ORM — typed queries, safe migrations
Auth	Session-based login with secure cookie management
Google Sheets	Live OAuth-connected sync via Replit Connector — no API keys to manage
Hosting	Cloud deployment on app.seated.pk with TLS, health checks, and uptime monitoring
Conflict Safety	Server-side booking validation — concurrent booking attempts are rejected at the database layer

WHAT SEATED DELIVERS
